

# Mashups and Modularity: Towards Secure and Reusable Web Applications

**Antero Taivalsaari**  
**Tommi Mikkonen**

**Sun Microsystems Laboratories**

[firstname.lastname@sun.com](mailto:firstname.lastname@sun.com)

# http://research.sun.com/projects/lively

The screenshot displays the Sun Labs Lively Kernel web browser interface. The browser window shows the URL <http://research.sun.com/projects/lively/index.xhtml> and a search bar with the Google logo. The main content area features a dynamic user interface with several widgets:

- JavaScript Code Browser:** A list of code snippets on the left, including `initialize`, `makeNewFace`, `reshape`, `startSteppingScripts`, and `setHands`. The `setHands` function is highlighted, showing its implementation:
 

```

ClockMorph.prototype.setHands = function ()
{
    var currentDate = new Date();
    var center = this.shape.bounds().center();
    var second = currentDate.getSeconds();
    var minute = currentDate.getMinutes()+second/60;
    var hour = currentDate.getHours()+minute/60;
    this.getNamedMorph("hours").setRotation(hour/24*360);
}
      
```
- Weather Widget:** A widget displaying weather information for San Francisco, California, including temperature (9°C / 48°F), wind speed (6 mph), wind direction (NW), pressure (1014mB, Rising), relative humidity (68%), and visibility (Good). It also includes a BBC Weather logo.
- Stock Widget:** A widget displaying stock market data from BigCharts.com, including DJIA (13,727.03, +0.74%) and NASDAQ (2,718.95, +0.47%). It also includes a section for DOW JONES, NASDAQ, NYSE, and S&P INX.
- Other Widgets:** A clock widget, a "Sun 3D Logo" widget, and a "Score: 0" widget.

The interface is designed to be dynamic and interactive, allowing users to explore and modify the code and widgets in real-time.

# Evolution of the Web

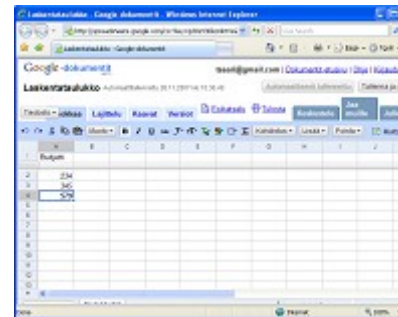

1) Simple pages with text and static images only  
(e.g., <http://www.google.com>)

2) Animated pages with plug-ins  
(e.g., <http://www.cadillac.com>)

3) Rich Internet Applications  
(e.g., [docs.google.com](http://docs.google.com))

What's Next?

# Web Applications – Implications

- Web-based software will dramatically change the way people develop, deploy and use software.
- No more installations!
  - > Applications will simply run off the Web.
- No more upgrades!
  - > Always run the latest application version.
- Instant worldwide deployment!
  - > No middlemen or distributors needed.
- No CPU dependencies, OS dependencies, ...
  - > The Web is the Platform.

# Unfortunately...

- The web browser was not designed for running real applications.
  - > It was designed in the early 1990s for viewing documents, forms and other page-structured artifacts – *not* applications.
  - > Programming capabilities on the web were an afterthought, not something inherent in the design of the browser.
- Various Rich Internet Application (RIA) technologies have been introduced recently to retrofit application execution capabilities into the web browser.

# Web Development vs. Conventional Software

## The Impedance Mismatch

Web Development	Conventional SW Development
<ul style="list-style-type: none"> <li>- Documents</li> <li>- Page / form oriented interaction</li> <li>- Managed graphics, static layout</li> <li>- Instant worldwide deployment</li> <li>- Source code and text favored</li> <li>- Development based mostly on conventions and “folklore”</li> <li>- Informal development practices</li> <li>- Target environment not designed for applications</li> <li>- Tool-driven development approach</li> </ul>	<ul style="list-style-type: none"> <li>- Applications</li> <li>- Direct manipulation</li> <li>- Directly drawn, dynamic graphics</li> <li>- Conventional deployment</li> <li>- Binary representations favored</li> <li>- Development based on established engineering principles</li> <li>- More formal development</li> <li>- Target environment specifically intended for applications</li> <li>- A wide variety of development approaches available</li> </ul>

# Landscape of RIA Technologies

## Browser-based

- Ajax
- Google Web Toolkit
- Sun Labs Lively Kernel

## Plugin-based

- Flash & Flex
- (Java FX, AIR)
- (Microsoft Silverlight)

## Custom runtime

- Java, Java FX
- Adobe AIR
- Silverlight

- Run in a standard browser
- No plug-ins needed
- Platform-independent
- Browser-based UI

- Browser plug-in required
- Custom UI

- Custom execution engine required
- Runs outside the browser
- Custom/native UI

**Technologies in the web browser serve as the lowest common denominator!**

# **Beyond Google Docs and Other Desktop-Style Web Applications...**

## **Software as a Social Mashup**

# Web 2.0 – What Is It Really About?

- *Interaction.* Bringing back some of the best qualities that desktop software had before the Web, such as direct manipulation, instant feedback, piecemeal display updates.
- *Collaboration.* Allowing the users to work with each other in a “social” fashion, and share the same data, applications and services over the Web, regardless of their physical location.
- *Mashups.* Being able to combine content available on the Web in novel ways.

# An Important Observation

- Web applications are **not** just conventional desktop applications running in the web browser.
  - > Not necessarily just word processing applications, spreadsheets, e-mail or instant messaging clients, ...
- The Web enables the creation of entirely new types of applications and services that combine content from other web sites dynamically.
  - > This would not have been possible with conventional shrink-wrapped applications distributed in binary form.

# Mashups

- *Mashup*: A web site that combines content from more than one source (multiple web sites) into an integrated experience.
- Mashups leverage the power of the Web to support worldwide sharing of content that would not have been easily accessible or reusable before the Web.
- In principle, the content to be combined can be anything (text, source code, maps, video, blogs, product reviews, price data, ...) as long as it can be meaningfully combined with other content.

# Examples of Mashups

- Chicago Police Department crime statistics mashup (<http://chicago.everyblock.com/crime/>)
- Parking availability mashups (e.g., <http://www.parkingcarma.com/>)
- Traffic tracking and congestion mashups (e.g., <http://dartmaps.mackers.com/>)
- Real estate sales and rental mashups (e.g., <http://www.housingmaps.com/>)

# Observations on Mashups

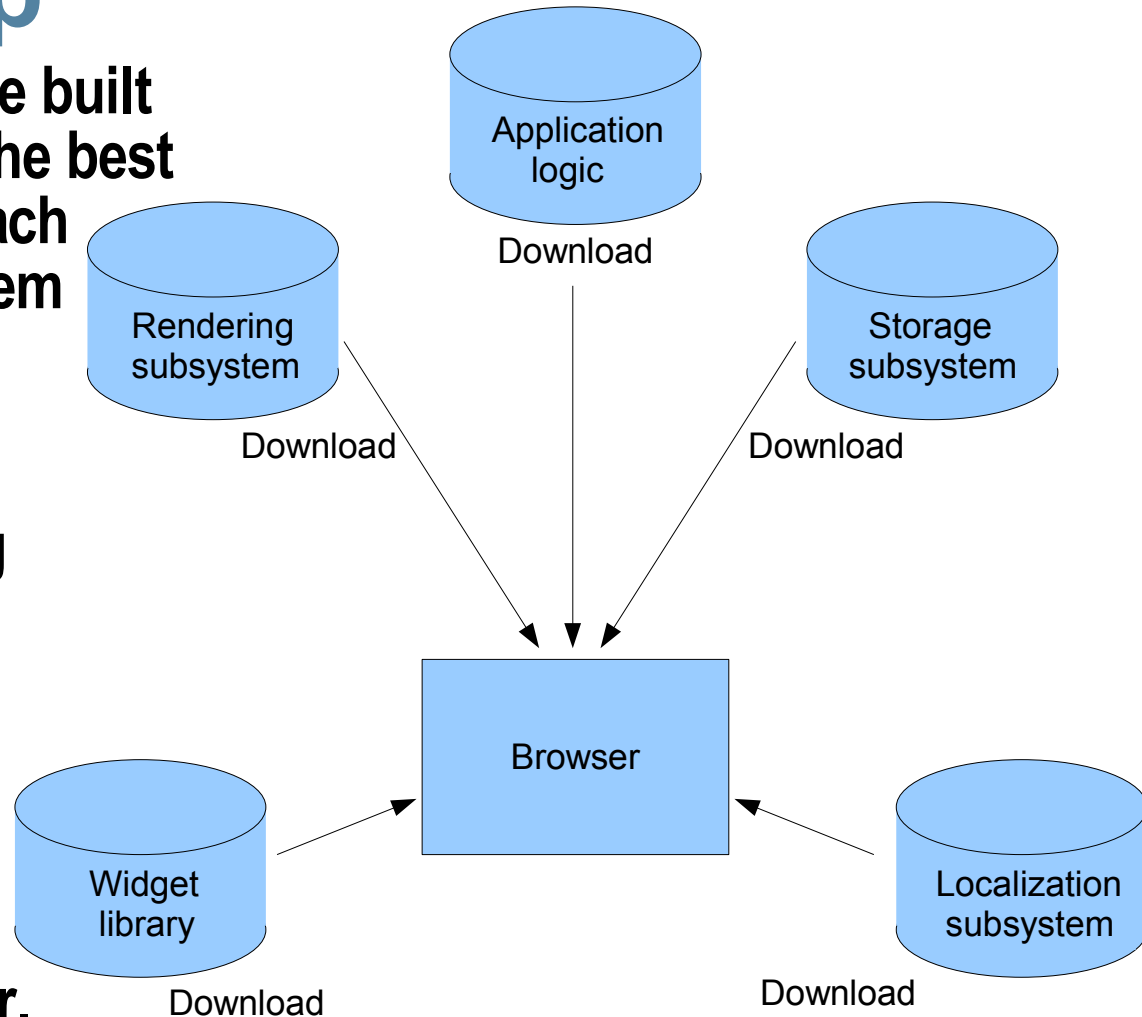

- Today, most mashups are built around *maps*.
- However, in principle the content can be anything as long as it can be digitalized and shared over the Web.
- Mashups are usually generated dynamically with no static linking; textual representations such as HTML, XML or JSON favored.
- In principle, it would be possible to build software as a mashup as well.

# The Future of Software as a “Social Mashup”

In the future, software will be built by dynamically combining the best available components for each purpose by downloading them dynamically from different web sites.

No static linking; everything downloaded on demand.

Software development will be an inherently social activity between developers who do not necessarily know each other.

**Today's web browsers do not support these kinds of applications yet!**

# Mashups vs. Modularity

- Modularity is an important *social* aspect of a system.
  - > Modularity is the enabling factor for large-scale software development and reuse.
  - > If there is only one developer, there would be little or no need for modularity.
  - > Modularity makes it possible for a large number of developers to work without interfering with each other.
  - > Without well-defined interfaces, implementation changes would be visible to everybody.
- The lack of proper modularity is a key deficiency (along with security issues) that prevents web application and mashup development in a truly social fashion.

# Software As a Mashup: Two Main Problems

- *The lack of modularity / well-defined interfaces.*
  - > Prevents developers from easily sharing and reusing code developed by others.
- *The lack of a flexible security architecture.*
  - > Prevents developers from easily and securely downloading and combining source code from multiple web sites across the planet.
  - > The *Same Origin Policy* restricts access to other web sites, see [http://en.wikipedia.org/wiki/Same\\_origin\\_policy](http://en.wikipedia.org/wiki/Same_origin_policy)

# Additional Problem Areas

- During our project, we have discovered problems in various areas related to the use of the web browser as an application platform:
  - 1) Usability and user interface issues
  - 2) Networking and security issues
  - 3) Browser interoperability and compatibility issues
  - 4) Development style and testing issues
  - 5) Deployment issues
  - 6) Performance issues
  - 7) Software engineering issues

# Additional Problem Areas

# Conclusions

- Like it or not, the Web is increasingly the platform of choice for advanced software applications.
- Web-based applications have major benefits: no installation or upgrades needed, instant worldwide deployment without middlemen.
- Web-based applications will dramatically change the way people develop, deploy and use software -> paradigm shift!
- Web technologies need to evolve in a direction that allows software to be created by dynamically combining the best available components from all over the world -> software as a “social mashup.”

# Thank You! Questions?
